

# JMX Flow (WDFW)

## **JMX Flow Processes**

1. A process to move data from current storage format into the staging database. This could be from paper via a user interface, or from a spreadsheet/database via a bulk load procedure/user-interface.
2. A process to extract the pertinent parts of the collected record to enable its consumption by the derivation process.
3. Derivation process for generating the production estimate.
4. A process to move the data currently in the staging database to the JMX database. This will also clean the staging database of data in preparation of the next cycle of data collection/derivation.
5. A process to synchronize the two JMX databases.
